

BDD Scenarios — Cash Kiosk Slot

Note: The below test cases are the translated into BDD format which later can be used as. feature file to run automated tests.

Feature: Core Win Verification

Scenario: Win amount shown matches the amount from the Demo call's response

Given a spin that results in a win, spun repeatedly if needed
When I capture the Demo call's response — the call that actually returns the win, not Settle (items/quantity only) and not a separate Spin call, since there isn't one
Then the displayed win amount matches the Demo response exactly, including currency formatting

Scenario: The server-determined outcome can't be contradicted by the reel animation

Given a spin is triggered
When I compare the timing of the API response against when the reel animation visually resolves
Then the API response arrives before or at the point the animation resolves, and the animation always matches that outcome

Scenario: Pre-spin and post-spin Customer State calls are each correct for their point in the flow

Given a spin is triggered
When I capture both the pre-spin and post-spin Customer State calls
Then each reflects the correct state for its point in the cycle — pre-spin before the bet is placed, post-spin after Settle has completed

Scenario: Balance doesn't update until Settle actually returns

Given a spin is triggered
When I watch the balance display and the network calls together
Then the balance only changes after the Settle call has completed, never before

Scenario: Buy call in the pre-spin sequence behaves correctly

Given the standard pre-spin call sequence
When I observe the Buy call across several spins
Then it behaves consistently with no errors; if it also drives a user-facing purchase feature, the cost is charged exactly once per purchase

Feature: Core UI Actions

Scenario: Basic spin completes correctly

Given sufficient balance
When I tap Spin
Then the reels animate and resolve to a coherent result, and the balance is debited by the bet amount at the start of the spin

Scenario: Auto play runs the configured count and stops correctly

Given Auto Play is enabled with a set number of spins
When it runs to completion, and separately when manually stopped partway through
Then it executes exactly the configured number of spins, stops immediately on manual interrupt, and also stops on a low-balance or bonus-triggering condition

Scenario: Max Bet sets the correct value when balance allows

Given a balance sufficient for the game's true maximum bet
When I tap Max Bet
Then the bet is set to the game's actual configured maximum

Scenario: Max Bet respects balance limits when balance is low

Given a balance below the game's true maximum bet
When I tap Max Bet
Then it caps at what's affordable or is disabled, without ever allowing a negative balance

Scenario: Balance display only changes at well-defined moments

Given a spin in progress or one that has just completed
When I observe the balance display continuously through the cycle
Then it only changes at spin-start and post-settle, with no flicker or premature update

Scenario: Winnings display resets correctly between spins

Given several consecutive spins with mixed outcomes
When I check the winnings field after each spin
Then it resets before each new spin and shows the exact correct amount, never carrying over from the previous spin

Feature: Compatibility

Scenario: Cross-browser functional check

Given the core spin-and-win flow
When I repeat it on Chrome, Safari, and Firefox mobile
Then the game loads, plays, and settles identically, with no layout breakage or missed API calls in any browser

Scenario: Device-specific checks

Given the core flow
When I repeat it at phone and tablet viewport sizes under both iOS and Android emulation
Then the layout adapts correctly at each size and no device/OS combination causes a crash or rendering issue

Feature: Continuity / Edge Cases

Scenario: Win animation can be interrupted without losing or duplicating the win

Given a win celebration animation is playing
When I tap rapidly, attempt to spin again, or navigate away and back
Then the correct win amount is still reflected in the balance, with no crash, freeze, or double-credit

Scenario: Extended play session stays stable

Given an extended sequence of 100 or more spins
When run in one continuous session
Then there is no performance degradation, memory-leak symptoms, balance drift, or state desync

Scenario: Balance can never go negative

Given a balance just below the current bet amount
When I attempt to spin or tap Max Bet
Then the spin is blocked or the bet auto-adjusts down, and balance never goes negative under any sequence of actions

Feature: Network / Sync Reliability

Scenario: UI never shows a result before the API has actually returned it

Given normal and network-throttled conditions
When I observe animation completion timing against API response timing across several spins
Then the UI always waits for the real response, showing a loading state if needed, rather than guessing or resolving early

Scenario: Game recovers gracefully from a network drop mid-spin

Given a spin is in progress

When the network is disabled mid-spin and later restored

Then no phantom win is awarded, the bet isn't silently lost, and the client resyncs to reflect the true server-side outcome on reconnect

Scenario: Backend interruption doesn't cause duplicate or lost settlements

Given a backend interruption during active play, simulated in a staging environment

When the backend returns

Then there are no duplicate settlements, no lost spins, and the client's balance/state resyncs correctly against the backend

Scenario: The full call sequence fires in the same order every time

Given several spins are played

When I capture the network calls for each

Then the order is always Customer State, Buy, Demo, Settle, Customer State, with the reel animation playing client-side between Demo and Settle rather than as its own call, and no reordering, skipping, or extra calls anywhere in the sequence
